

Optical image correlation: exploiting the Sentinel-2 archive for Earth Surface Deformation monitoring.

Floriane Provost, J.-P. Malet, D. Michéa, P. Bally

ForM@Ter-MDIS Workshop – Strasbourg and La Petite-Pierre, October 14-18, 2019

ESA UNCLASSIFIED - For Official Use

# EO for monitoring surface deformation

#### Motivations

- EOs are key datasets for better understanding, modelling and forecasting geohazards such as volcanoes, landslides or glaciers.
- Open medium resolution constellation with short revisit time are now available.
- Processing this amount of data offers numerous perspectives for scientific communities...but also challenges.

Kang et al., 2019

ESA UNCLASSIFIED - For Official Use

# Optical observations for monitoring surface deformation

#### Space borne InSAR

- Sensitve to motion in the LOS i.e. sensitive to EW and vertical motion. Poorly sensitive to NS motion.
- Millimetric accuracy.
- Monitoring of very small (mm) to cm motion. In cas of larger motion, decorelation usually prevents to monitor the deformation.
- Non sensitive to cloud cover.

#### Space borne Optical Image Correlation

- Sensitve to Horizontal movement, Non sensitive to vertical motion.
- Sup-pixel accuracy (in general metric to cm).
- Monitoring of large movement (metric). Smaller movement can also be measured depending on satellite pixel size.

Figure 3. Yearly rate map of the Fagraskógarfjall landslide between July and November 2017. Green represents relatively stable areas while the red-yellow region highlights significant slip of the landslide. Up to 2 m per year of slip may have occurred in some parts of the landslide. © CGG 2018. Images contain modified Copernicus Sentinel data (2018).

# Method – Optical offset tracking

#### **MPIC – Multi-Pairwise Image Correlation**

#### 1. Cloud mask

Computed with python function *Fmask* (Zhu, Z. and Woodcock, C.E., 2015) for each Sentinel-2 acquisition, then combined.

#### 2. Correlation

Computed with MicMac for all pairs.

#### 3. <u>Deramping</u>

Correct systematic offset resulting mainly from translation and rotation.

#### 4. De-striping

Correct small systematic image offsets which manifest as along-track striping artefacts which are particularly visible in the EW component but can also be observed in the NS component (for Sentinel-2). This is due to staggered sensor arrays of push broom satellite such as Sentinel-2.

# Conclusion and perspectives

#### Conclusion

Sentinel-2 time series of the ground motion provides key information:

at the scale of one landslide to understand the acceleration phase.

at a regional scale, to detect these activations

The current geometry of the L1C products contains distortions in the mountainous areas making difficult the processing of long time series when considering correlation between consecutive acquisitions

#### Perspectives

Revise the scheme to compute the pairs by increasing the temporal baseline.

Correction of the topographic offset is an option as well as the reprocessing of the Sentinel-2 archive with a better DEM (30m) and the GRI to improve the geolocation of the pixel through time.
